U, n, -

We can also use TPMMS

- · Do phase one of R
- · Do phase one of S.
- · Phase 2: do both Rand S at the same time:

Read 1 block of each section of R and S at a time:

> do operation on typer in

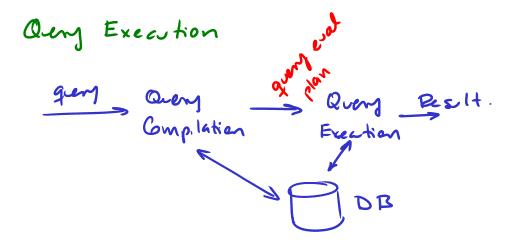

We need B(R) + B(S) < M

for second pass:

> Memon regreed is alprox

$$B(R) + B(s) \leq M^2$$

Cost: 3(B(R) + B(S)

Queny Compilation

- a) Parsing. A parse tree is constructed. Create an algebraic expression.
- b) Query Rewrite:
- · Several equivalent queny expression
- c) Physical plan generation
  - . Each expression is converted to an evaluation plan by indicating the alg. to use.
- b) and c) are the gren optimizer

  => find best greny plan:

- 1) Which algebraic expression is the one leading to the most efficient alg.
- 2) For each operation in the expression which alg. will be used to answer it.
- 3) How should each operation pass data to the next operation.
- 4) How are the relations going to be accessed.

SELECT \* from R natural Join S WHERE b = 5

Equivalent Expressions

Deplicate elimination S(R)

· Sort R using TPMMS
· Dunng second phase, output only
first tiple of each set of diplicater
Mem regimed:

 $B(R) \leq M^2$ 

Cost: 3B(R)

Group By T

Use TPMMS to sxt by aggr. attributer like E(R), during second phase for each group of tuples in output compute aggregation output result

Regimes one pass of tipler in group. Memory required for compating agg. is less than 1 block.

Total mem regined B(R) \( \Leq \mathbb{M}^2\)
Cost: 3B(R)

Memony regard

> Approximately BCR) < M2

Gs+:

Phase 1: B(R) Read B(R) Write.

Phase 2: B(R) Read

Assume Read = Write

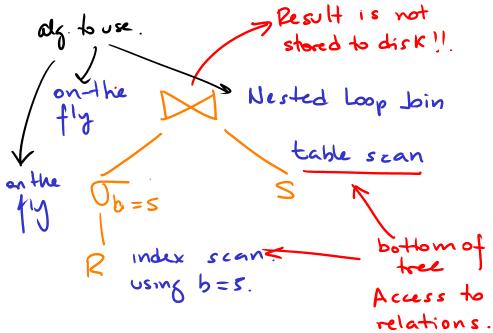

⇒ 3B(R)

and output is sented.

We can generalize # pases to.

But usally with a decent amount of mening we can sert very large relations in 2 passes.

Annotate tree with algorithms and access methods

Estimate cost.

⇒ choose fastest!

Access to type:

· Segrential scan of heap of Rel.

· Using an index to scan a abset of toples of R (index scan)

Realt of greny:

· Kept in memory.

## Iterators:

- · Many operations access only, one type at a time.
  - · read type.
  - · inspect
  - · dispose
  - . read next tople . .

Open () - initiates the process Get Next () - return next tiple close () - ends process

## Example:

Ta  $O_{b=3}$  R

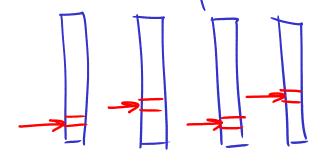

Ta on the fly  $O_{b=3}$  on the fly  $S_{b=3}$  sean of R

Thank of ican be implemented as iterators
of inspects one tiple at a time, sends one
tiple at a time to IT
No need to store any tiple is memory

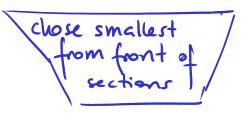

If # sorted sections < M-1 then

## Phase 2:

- · Merge serted sections by reading one block of each section at a time.
- · Use 1 block for output.

sections
of
at most
M-1block,

output sorted tipler.

if # sections > M we might need 3 or more phaser Two pass algorithms based on sorting Algorithms that read data twice.

· Read types
· Process types
· Write typer to disk

· Read types

· Process tyles.

soutpet realt )

Sorting T

· By serting re can implement other operations (eg. N, 8, M).

Iwo Phase Multiway Merge Sort TPMMS · Alg. to sort large relations.

·Phase 1:

For each M blocks of R Read M blocks.

write back to temp. storage.

This creates B(R) serted sections

Parameters to measure cost

M. Amount of memory available in number of blocks

B(R) # of blocks used by heap of R

IRI # of types of R (book uses

V(R, a) # of different value of atta in 12

In general:

V(R, [a1, az ... an]) = | \ \ a1, az ... an R | => # of different values for tiple

Git Model

· We assume that the mager component of ort is I10

· Git of read equal to cost of write · Git of random accurs of pages equal to cost of sequencess.

Algorithms to answer gener.

2 main classifications.

a) based on type of algorithm:

1) Sorting based

2) Hash based

3) Index based

b) based an difficulty.

1) One-pasi: Delaturs are read only once.

2) Two passer.

· Read data (1st pass)

· Proces c.

·Write data.

· Recd data agan. (2nd pass).

End pass might read diff number of blocks than 1st pass.

3) three de more passer. (needed for very large relations). · Generalization of Two passes.

Because tables are usally large we approximate to:

Cost:  

$$B(R) \cdot \left[ \frac{B(S)}{M} \right] \simeq \frac{B(R) \cdot B(S)}{M}$$

It does not really matter which relation we read in the outside loop. But outside table only read once. That might affect which table is outside.

Block based Nested Join. Creneralization of 1 pass join · What if no relation fits in memory? Assime: B(S)'>M. outside bop B(R) >M For each M-1 blocks of S Read blocks and organize them in mem. read types in block inside for every type T in R loop. I find matching tiples in read blocks of S. Each block of Ris read

B(s) timer.

We also need to read S.

$$\left\lceil \frac{B(s)}{M} \right\rceil$$
,  $B(R) + B(s)$ 

One Pass Alg.

1) Tuple-at-a time TI, o · We can read one block at a time. =) use one menneng buffer.

> The Read one block at atome, · in spect each tiple, 2 · Repect.

if he received types from another operation, one type at atome with no need for buffering. (on the fly " no menny needed)

Ila. on the fly. 1 · Receive tiple from M wa iterator. · Pepeal.

No block in memory

By assure 1 block for simplicity's Sake.

Other one pass unary specators. Deplicate elimination (E) · Read each tyle. . If we have seen it ignere . Otherwise output and keep track ofit. We need to keep a copy of each district tople. at mort types \_\_\_\_ available distanct. (iterator or from R heap) We do not need block for output. > types in realt offer immediately. We can do 8 P in one pass as long as: B(6(R)) < M-1. Book user.  $B(S(R)) \leq M$ because M>>1 So use latter for consistency.

Summary of I pass algorithm. Approx blocks of M regimed M, J, UB B(R) 8 B(R) + B(S) $\cup$ ,  $\cup$ 4 min (B(R), B(S)) -B, ⋈, X order by is a variation of 8, 5 denoted 7

We always read smaller table into M To compte R-S, R-05. Read S
for every tiple to in R
if to not in S
output
(for — also keep track of those
output)

To compte S-R, S-BP for - removall diphreater at the same time. For every type t in R if t in S remae from S for -3 remove one approache only Loutpt typer left in S

Dt, but bue know B(8(2)) without calculating & (R) first: >> State. R (a1, a2 ... an) We can use V(R, a... an) and the size of the type in R to calclete & (P). Group By:

Generalization of of (R) Remember S(R) = Ya...an R

tar X (att litt) R

We need to keep track of:

· Each different value of <attlint> · Info needed to compute <explist>.

- · min (x) / Keep ament min/max max(x)
- · sum (x) · Keep ament sum
- · cont(x) Veep wrent comt
- avg (x) Veer both ament count and sum.

We cannot out pA types will be have read all inpt types.

·We must also cocate access structures in memory (hash tables, b+ trees) to efficiently find group tuple belongs to.

. In general

- . The amount of money regard per group is small.
- . Propartional to the number of different groups.

| 8 dimai P X V(R, an... ai)

M

RMS = Op (EXS)

Since we can do op anthefly

The anthe fly (deer not need memory).

But join is common, so DBMS optimize

Read S
for ever, type t in R
for every type s in S
if tand s satisfy P
output join(t,s)

Liké N, U, etc. Le load smaller table into memony.

That algorithm is different depending on which table is smaller: (), ()<sub>B</sub>,  $\times$ ,  $\bowtie$ , -, -<sub>B</sub>.

. All commutative operations.

· Keep smaller table in memory (plus data structures for fact accers).

· Plus at most one block for other tenle:

One parr if, approximately:

 $\min(B(R),B(S)) \leq M$ 

Specifically for each of these operations. Because they are commitative, assure  $B(S) \geqslant B(S)$ 

Read S, organize in dete structure. for every tiple tim ? if this safet tif reeded otherwise output to first time only.

for every tiple s in S

compete cross product, output.

We can do it in one pass if he have enough memory to

· hold all différent groups · deta structures for quick access to anougs.

· any data regreed to compute grouping

In general size of tiple of realt much smaller than enjoind tiple.

So us simplify We can de group- by in one pars B(R) < M

One Pass alg. for known operations.

In practice set operations of thotyper:

· The sets: Noduplicates (default).

· Bags: deplicates.

UNION
INTERFECT ALL
EXCEPT

⇒ Represented UB, ∩B, -B

TABLE RUNION ALL TABLES

Rest contains all types in R plus
all types in P.

if a typle in hais madphicaterin?

and n deplicates in S

rest contains min(min) deplicates

of typle.

TABLE R EXCEPT ALL TABLES

if a typle in has madphicaterin R

and n deplicates in S

reselt contains min(m-n, 0)

(2)

UB

· Similar to TI:

· We only need to inspect one type at a time.

M = 1. regardless of size of imput.

· Permaes diplicater:

· Egnalento. & (RUDS)

The book is wrong. It states he only need to read Sin M-1 and do one-type-at-a time for R (page 716)

We can do in one pass if S(RUBS) ≤ M

We can approximate to:

δ(B(R))+ δ(B(S)) ≤ M

We can remae diplicates as we read troves:

if typle already read, ignere otherwise 4 output ladd to read typles.
